Debugging Features

Introduction

- Your educational OS project will target μ MPS2—a hypothetical streamlined computer architecture designed on purpose for this kind of application
- You will be using an emulator to run your programs, of course
- In this tutorial, we are going to cover:
 - The essentials of the μ MPS2 architecture
 - The development environment: the cross-development toolchain, μ MPS support libraries, etc.
 - Emulator usage

Elements of the UI

Debugging Features

Processor Architecture

- μ MPS2 processors implement a slight superset of the base MIPS-I architecture.
- Historical note: MIPS-I is the name retrospectively attributed to the ISA of the earliest MIPS processors—the R2000 and the R3000.
- μ MPS2 differs somewhat from the R2000 in the system control coprocessor (CP0) interface:
 - It introduces two modes of operation of the MMU
 - Physical memory mode: address translation is not performed
 - Virtual memory mode: address translation is performed for all addresses, apart from those in the MMIO/ROM range
 - It includes an integrated interval timer (see the **Timer** CP0 register)
- New instructions: **cas** (compare-and-set) and **wait** (wait for interrupt)

Devices

- μ MPS2 supports 5 types of peripheral devices:
 - disks
 - tapes
 - network adapters
 - printers
 - terminals
- Up to eight instances of each device type may be installed
- Device controllers support an interrupt-driven programming model
 - Devices of the same type share a single interrupt line
- All device controllers use MMIO and expose a similar programming interface

Multiprocessor Support

- A μ MPS2 machine supports up to 16 processors
- Processors are controlled via a set of **machine control registers**
- μ MPS2 includes a multiprocessor interrupt controller (MPIC)
 - The MPIC controls distribution of interrupts to available processors
 - For each interrupt source, the programmer can specify the policy which determines a target CPU for an interrupt from the source in question
 - The above is accomplished by programming a structure called the **interrupt routing table** (IRT)

The BIOS

- A μ MPS2 machine needs to be provided with some basic ROM code in order to operate at all
- Most importantly, the memory region onto which the ROM code is mapped contains the exception entry points
- Two ROM modules must be supplied: a **bootstrap** ROM image and an **execution** ROM image
- The default execution ROM image is **exec.rom.umps**, installed under `<prefix>/share/umps2`
- Some convenient higher-level services are implemented by the **exec.rom.umps** code:
 - A more elaborate exception-handling scheme
 - A segmented/paged virtual memory scheme

Hello μ MPS

3 Using the Emulator

Elements of the UI

Debugging Features

Programming for μ MPS2

- You are expected to implement your OS in the C language
- As we have seen, μ MPS2 is centered around the MIPS architecture
- The above implies that we can use unmodified compilers which support a MIPS back-end to target μ MPS2
- At the moment, the most viable (and perhaps the only) option is given by GCC

The Cross Development Toolchain

- You cannot use the host's compiler and associated set of development tools you (may) have installed on your system to build programs for μ MPS2/MIPS.
- Note: a single GCC/Binutils build supports a single target
- We need separate tools, configured and built for a MIPS target:
 - The compiler (GCC)
 - GNU Binutils: `as`, `ld`, ...
- We refer to the above as a **cross toolchain**

Installing the Toolchain for Ubuntu Users

- There is an archive with μ MPS2-related packages for Ubuntu:

<https://launchpad.net/~jonjic/+archive/umps2>

- Simply add the relative **sources.list** entries to your system (see the above page for details).
- The toolchain consists of the following packages:
 - **umpsxt-binutils-mipsel**
 - **umpsxt-gcc-mipsel**
- Installed binaries follow the

mipsel-elf-tool

naming scheme; e.g., **mipsel-elf-gcc**,
mipsel-elf-ld, ...

Building the Toolchain

- Binutils:

- Configure as:

```
configure --prefix=<prefix> \  
          --target=mipsel-elf \  
          --disable-nls
```

- Make and install as usual

- GCC:

- Configure as:

```
configure --prefix=<prefix> \  
          --target=mipsel-elf \  
          --enable-languages=c \  
          --without-headers \  
          --disable-nls
```

- We don't need to build/install all components:

```
make all-gcc all-target-libgcc  
make install-gcc install-target-libgcc
```

3 Using the Emulator

Elements of the UI

Debugging Features

libumps

- The emulator ships with a small utility library called **libumps**
- **libumps** provides:
 - Abstractions for BIOS service requests:
`LDST()`, `INITCPU()`, ...
 - CP0 register accessors: `getPRID()`, `getSTATUS()`,
`setSTATUS()`, ...
 - Simple wrappers for some processor instructions:
`TLBWR()`, `WAIT()`, `CAS()`, ...
- All of this is in no way essential, but it's convenient, especially if one is not familiar with the MIPS assembly language

Using libumps in Your Programs

- Single header file: `libumps.h`
 - Installed in `<prefix>/include/umps2/umps`
 - Best practice: add `<prefix>/include/umps2` to the list of searched dirs and use
`#include "umps/libumps.h"`

- Implementation: `libumps.S`

- Installed in `<prefix>/share/umps2`
- Assemble and link to your kernel executable:

```
VPATH = $(UMPS_DATA_DIR)
```

```
...  
%.o : %.S
```

```
$(CC) $(CFLAGS) -c -o $@ $<
```

```
kernel : ... libumps.o ...
```

- Where `UMPS_DATA_DIR` was set to the above dir

Backward Compatibility Notes

- The distribution also includes a pre-assembled relocatable module (`libumps.o`), installed under `<prefix>/lib/umps2`
- This is only done for backward compatibility reasons!
- This file is tied to a specific flavor of a specific MIPS ABI variant
 - For details, see the output of `readelf -h libumps.o`

Hello μ MPS

3 Using the Emulator

Elements of the UI

Debugging Features

μ MPS .aout/.core Object File Formats

- A number of features are included with μ MPS for user's convenience
- Among these is a specification for a simplified executable file format, along with the relative build-time/run-time support
- Two flavors of the executable format are provided:
 - The **.aout** format is aimed at regular executables
 - The **.core** format is aimed at kernel executables
- The **umps2-elf2umps** utility converts ELF object files to μ MPS object files:
 - ELF relocatable modules can be converted to μ MPS ROM images
 - ELF executable files can be converted to .aout/.core files

Linker Scripts for .aout/.core Executables

- Part of the support for .aout comes in terms of GNU ld linker scripts
- Each variant of the format has an associated linker script:

`umpsaout.ldscript`

Standard linker script for .aout executables.

`umpscore.ldscript`

Standard linker script for .core executables.

- The scripts are installed in `<prefix>/share/umps2`
- When using these scripts, the resulting ELF executable conforms to the memory layout requirements of the .aout format.

Elements of the UI

Debugging Features

Program Startup

- Before your `main()` function can be called, the program environment has to be properly set up (e.g. critical registers, such as the stack pointer or the `$gp` register, have to be initialized).
- μ MPS2 includes startup modules which should be adequate for most projects:
 - `crtso.S` Startup code for .core executables
 - `crti.S` Startup code for .aout executables
- The same backward compatibility/deprecation notes apply as for libumps!

Miscellaneous Headers

Hello μ MPS

3 Using the Emulator

Elements of the UI

Debugging Features

MIPS ABIs and Related Issues

- A number of GCC options control MIPS-specific aspects of code generation
- The default values of these parameters can differ, and depend on how GCC itself was configured
- For example, in many cases GCC generates SVR4/Linux-style position independent code by default
 - While certainly good for its intended use, this is completely inadequate for your kernel!
- Rather than relying on compiler-provided defaults (in “cargo cult” fashion), learn to control code generation as appropriate

Sensible Compiler and Linker Flags for an OS Kernel

- GCC:
 - ffreestanding
 - mips1
 - mabi=32
 - mno-gpopt -G 0
 - mno-abicalls -fno-pic
- Linker (ld):
 - G 0
 - nostdlib

Debugging Features

Hello World in μ MPS2

- There is a “hello world” example included in the μ MPS2 source distribution.
- The **Makefile** sums up part of the things we have covered thus far.

```
[tjonjic@soyuz hello-umps]$ ls
```

```
hello.c  Makefile
```

```
[tjonjic@soyuz hello-umps]$ make
```

```
mipsel-elf-gcc -ffreestanding -ansi -mips1 -mabi=32 -mno
```

```
mipsel-elf-gcc -ffreestanding -ansi -mips1 -mabi=32 -mno
```

```
mipsel-elf-gcc -ffreestanding -ansi -mips1 -mabi=32 -mno
```

```
mipsel-elf-ld -o kernel hello.o crtso.o libumps.o -G 0 -
```

```
umps2-elf2umps -k kernel
```

```
[tjonjic@soyuz hello-umps]$ ls
```

```
crtso.o  hello.o  kernel.core.umps  libumps.o
```

```
hello.c  kernel  kernel.stab.umps  Makefile
```

- **kernel.core.umps** is the .core kernel executable, ready to be loaded and run

Machines and Machine Configurations

- A μ MPS2 machine is described by a **machine configuration** file
- Machine configurations specify all user-settable machine parameters:
 - Number of CPUs and their characteristics (frequency, TLB size)
 - Installed RAM
 - Installed devices and the associated device files
 - ROM images
 - ...
- Machine configurations can be edited entirely within the emulator UI
 - Internally, these files employ a JSON-based syntax
- At any time, only a single machine configuration may be active (in a single instance of the emulator)

3 Using the Emulator

Elements of the UI

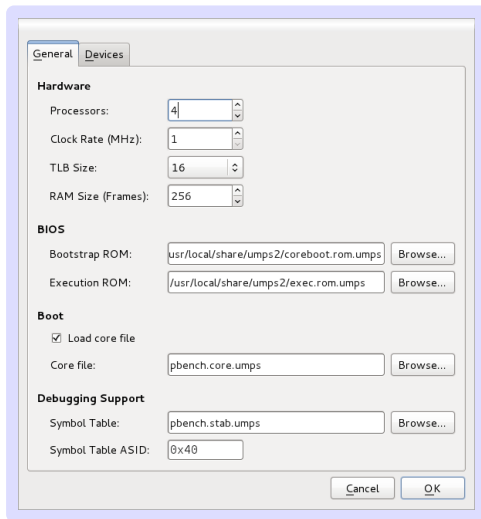

Debugging Features

Debugger Support in μ MPS2

- The emulator includes fairly complete debugging support:
 - Breakpoints
 - Suspects
 - Commonly known as “data breakpoints”, or “watches”
 - Machine execution is suspended on a read or (more commonly) write access to a memory location in a specified range
 - Memory tracepoints
- Machine execution is (almost) entirely deterministic
 - Under equal device input conditions, two emulation runs of a single machine will be identical
- Certain features aid debugging parallel systems
 - For example, it is easy to identify which CPU triggered a particular breakpoint or suspect

Memory View

Traced memory regions may be displayed in two ways: ASCII and hex; the selected region may be edited in-place.

Debugger Variables and Workflow

- A typical debugging session consists of one or more iterations of the following steps:
 - A condition that exhibits the bug is triggered, and an attempt is made to infer its cause
 - The required change to the source is applied, and the program is recompiled
 - The machine is reset (to reload the kernel)
- After recompilation, the old memory addresses associated with breakpoints might not be correct
- The emulator attempts to relocate breakpoints/suspects/tracepoints to the correct locations
